

[CarRecall](#) specification example

This example shows how Mango exposes cases splits to the user, if desired. Once generated, the specification may be navigated by opening folders in the Mango Explorer and following links in the revealed specification views.

Start by [loading](#) the FirstYearCode project.

On MacOSX, go to Eclipse>Preferences>"Mango Preferences". For other operating systems: Window>Preferences>"Mango Preferences".

Hit "Restore Defaults", in particular, "Suppress advice dialogs" and "Do not pause for case-splits" should be unchecked.

Hit OK to close the preferences.

In the Package Explorer, in the FirstYearCode project, open src/firstYearCode/CarRecall.java.

In the [CarRecall](#) editor, double-click on "[CarRecall](#)" in the class declaration line "public class [CarRecall](#) {}". This will select both [CarRecall](#) and the [CarRecall](#) editor tab.

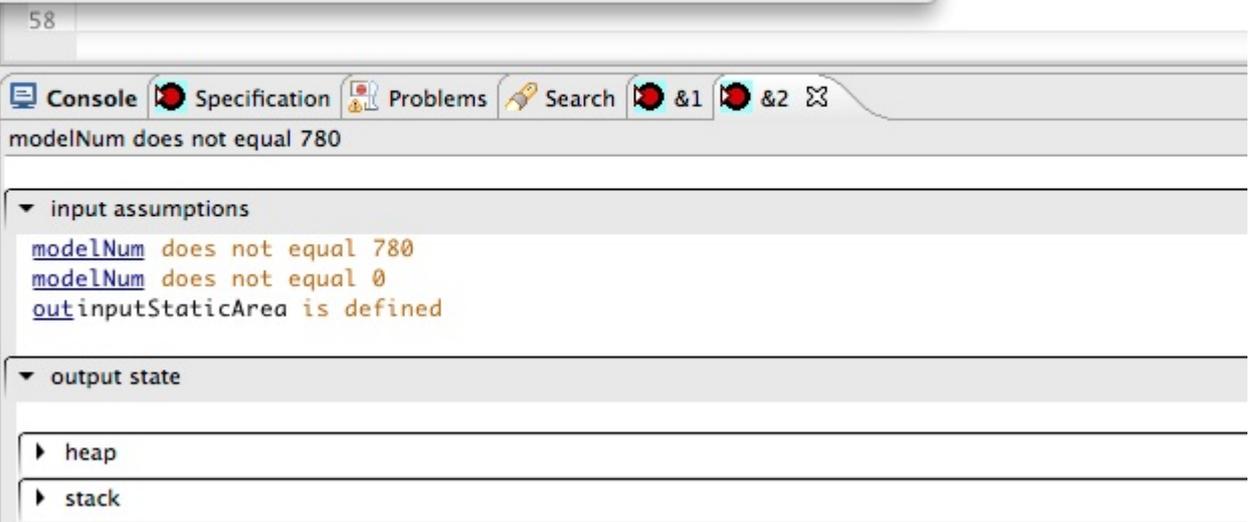

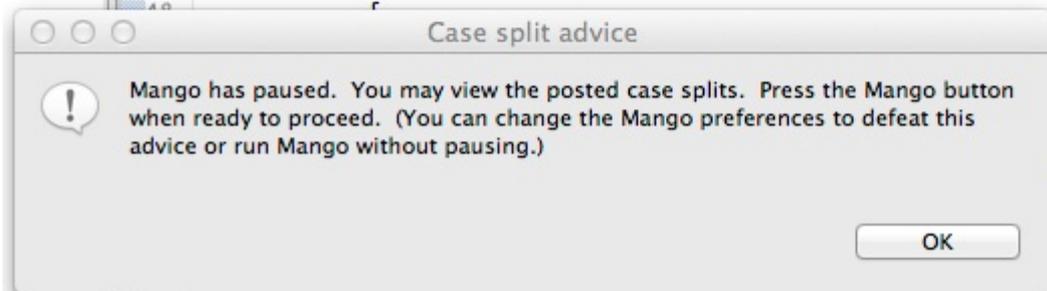

Right-click, Mango>populate. When the [Mango button](#) becomes green, right-click, Mango>run.

At the first case split, Mango will notify the user of a pause. (see figure)

```

32 public class CarRecall {
33     public static void main(String[] args){
34         int modelNum;
35         Scanner input = new Scanner (System.in);
36         do{
37             System.out.println("Enter the car's model number or 0 to quit: ");
38             modelNum=input.nextInt();
39
40             //test if car is defective
41             if ((modelNum==119)||(modelNum==179)
42                 ||((modelNum>=189)&&(modelNum<=195))
43                 ||(modelNum==221)||(modelNum==780))
44             {
45                 System.out.println("Your car is defective. It must be repaired.");
46             }
47             else if (modelNum==0)
48

```

Click OK, the [Mango button](#) will turn green. After a while it is easier just to be aware of when the [Mango button](#) changes color and not bother with the notification. Check "Suppress advice dialogs" to defeat notification in the future, if desired.

The line of source code corresponding to the case split has been highlighted. Observe the two cases, named &1 and &2, by clicking on their tabs. Each specification view is a functional description, and as such has two parts, "input assumptions" and "output state". For the "modelNum equals 780" case, the heap may be opened to reveal that "Your car is defective" has been appended to the "out" buffer. (see figure).

```

40 //test if car is defective
41 if ((modelNum==119)||(modelNum==179)
42     ||(modelNum>=189)&&(modelNum<=195))
43     ||(modelNum==221)||(modelNum==780))
44     {
45         System.out.println("Your car is defective. It must be repaired.");
46     }
47     else if (modelNum==0)
48     {
49         System.out.println ("Program terminated.");
50     }
51     else
52     {
53         System.out.println ("Your car is not defective.");
54     }
55 }while (modelNum!=0);
56 }
57 }
58

```

modelNum equals 780

input assumptions

- modelNum equals 780
- outinputStaticArea is defined

output state

heap

- <localVar> at unresolved location
 - outinputStaticArea.buffer=outinputStaticArea.buffer + Your car is defective. It must be repaired.<nl>

stack

Likewise, in the case "modelNum does not equal 780", the heap contains "Your car is not defective". So far so good, but what happened to the case modelNum==0, yielding "Program terminated". The short answer is that Mango hasn't forgotten about it, but isn't ready to consider it either. More specifically, Mango currently is building the specification for the loop body. The case modelNum==0 is a loop termination condition which does not yield a state transition for the loop body, so it is not relevant at the moment.

Spend some time assimilating the correspondence between procedural programming, the java code, and functional programming, the specification views. When you are ready, hit the [Mango button](#) so that Mango can proceed to the next case (see figure).

```

38     modelNum=input.nextInt();
39
40     //test if car is defective
41     if ((modelNum==119)|| (modelNum==179)
42         ||((modelNum>=189)&&(modelNum<=195))
43         ||(modelNum==221)|| (modelNum==780))
44     {
45         System.out.println("Your car is defective. It must be repaired.");
46     }
47     else if (modelNum==0)
48     {
49         System.out.println ("Program terminated.");
50     }
51     else
52     {
53         System.out.println ("Your car is not defective.");
54     }
55     }while (modelNum!=0);
56 }
57 }
58

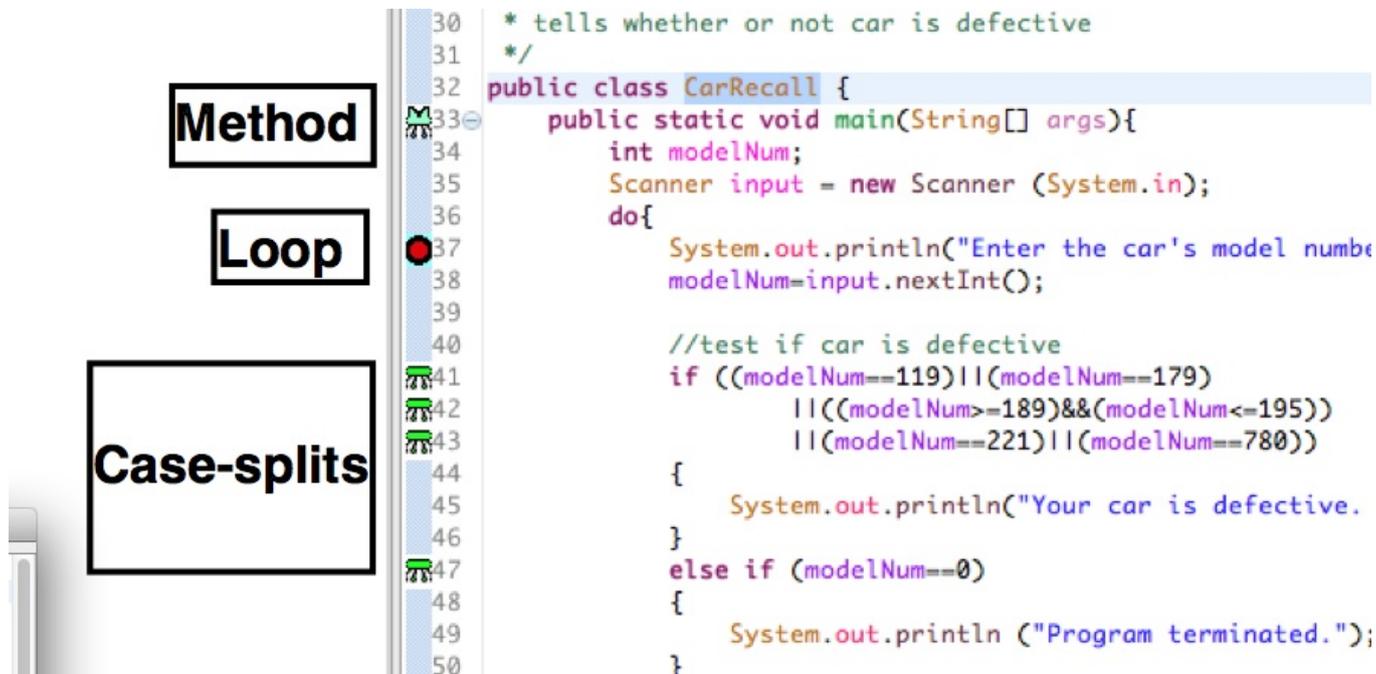

```

Observe that if modelNum does not equal 221, then execution drops through to the case Mango has already analyzed. This is because when we read code, we proceed top down in execution order. But the Mango functional analysis is always bottom up in the reverse of execution order. Put more simply, Mango starts at the end and works backwards through the case-splits. Notice the input assumptions "Does modelNum equal 780?". The technical interpretation of this assumption goes like this: "This case satisfies the input assumptions for the nested case "Does modelNum equal 780". The reason for this shorthand notation is pragmatic. To explicitly say what those assumptions are quickly leads to exponential growth in the size of the specification. Trust me on this, I have been there. Fortunately, there is a simpler, more useful interpretation: "The output state for this case will have variables in it referencing the nested case "Does modelNum equal 780?".

Indeed, observe that the heap has such a variable, "var1". Go ahead and click on it now (see figure).

A new panel appears for this view which give a reprise of the heap values for the nested case, tied to the possible input assumptions for that case. In general, if there is any doubt as the the validity of the values a variable may achieve in any given situation, it is always possible to open it up and see what is going on. If you find yourself doing this for more than two or three levels, then its possible that the code is not very well thought out, or perhaps you don't have a good grip on the nested cases in the first place.

The Mango analysis will continue enumerating case splits, but for now let's fast-forward to the end of the specification. In the Mango preferences panel, check "Suppress advice dialogs" and "Do not pause". Now press the [Mango button](#), causing Mango to run without interruption. You can monitor the progress of the run by viewing the console window. During the run, icons for the various case-splits will appear. Near the end of the run, a "loop icon" will appear in the source code icon gutter, and then finally the method icon (see figure).

You can click on these icons and further explore the various components of the specification. The procedure is the same as in the [Hello World](#) example. But there is lots more to investigate.

The [CarRecall](#) specification is stored in the file system upon completion of the run. This is so the information will be readily available to any code which depends on [CarRecall](#). In the event you wish to replay the specification, you need to clean out this information. See [replay an existing spec](#) for instructions on how to do this.
