

How to swap in individual modules from a different MangoHome (storeConfig regeneration)

All of the considerations of coarser [MangoHome/MangoSystem swap](#) apply to this case, with one additional issue. The file `MangoHome/store/storeconfig.zip` maintains a mapping which is required for the proper encoding and decoding of native file system names. In the case of individual modules swapped into a MangoHome, this file should be deleted. It will then rebuild itself during synchronization. Failure to do so may lead to very subtle inconsistencies.

It should be noted that a module is the smallest unit that can be moved. Moreover, the pathname of the parent folder must be identical in both source and destination MangoHome.
